# Cluster Similarity: MAX or Complete Linkage

- Similarity of two clusters is based on the two least similar (most distant) points in the different clusters
  - Determined by all pairs of points in the two clusters

	I1	I2	I3	I4	I5
I1	1.00	0.90	0.10	0.65	0.20
I2	0.90	1.00	0.70	0.60	0.50
I3	0.10	0.70	1.00	0.40	0.30
I4	0.65	0.60	0.40	1.00	0.80
I5	0.20	0.50	0.30	0.80	1.00

# Hierarchical Clustering: MAX

**Nested Clusters**

**Dendrogram**

# Strength of MAX

**Original Points**

**Two Clusters**

- **Less susceptible to noise and outliers**

# Limitations of MAX

**Original Points**

**Two Clusters**

- **Tends to break large clusters**
- **Biased towards globular clusters**

# Cluster Similarity: Group Average

- Proximity of two clusters is the average of pairwise proximity between points in the two clusters.

$$\text{proximity}(\text{Cluster}_i, \text{Cluster}_j) = \frac{\sum_{\substack{p_i \in \text{Cluster}_i \\ p_j \in \text{Cluster}_j}} \text{proximity}(p_i, p_j)}{|\text{Cluster}_i| * |\text{Cluster}_j|}$$

- Need to use average connectivity for scalability since total proximity favors large clusters

	I1	I2	I3	I4	I5
I1	1.00	0.90	0.10	0.65	0.20
I2	0.90	1.00	0.70	0.60	0.50
I3	0.10	0.70	1.00	0.40	0.30
I4	0.65	0.60	0.40	1.00	0.80
I5	0.20	0.50	0.30	0.80	1.00

# Hierarchical Clustering: Group Average

**Nested Clusters**

**Dendrogram**

# Hierarchical Clustering: Group Average

- Compromise between Single and Complete Link
- Strengths
  - Less susceptible to noise and outliers
- Limitations
  - Biased towards globular clusters

# Cluster Similarity: Ward's Method

- Similarity of two clusters is based on the increase in squared error when two clusters are merged
  - Similar to group average if distance between points is distance squared
- Less susceptible to noise and outliers
- Biased towards globular clusters
- Hierarchical analogue of K-means
  - Can be used to initialize K-means

# Hierarchical Clustering: Comparison

MIN

MAX

Group Average

Ward's Method

# Hierarchical Clustering: Time and Space requirements

- $O(N^2)$  space since it uses the proximity matrix.
  - $N$  is the number of points.
- $O(N^3)$  time in many cases
  - There are  $N$  steps and at each step the size,  $N^2$ , proximity matrix must be updated and searched
  - Complexity can be reduced to  $O(N^2 \log(N))$  time for some approaches

# Hierarchical Clustering: Problems and Limitations

- Once a decision is made to combine two clusters, it cannot be undone
- No objective function is directly minimized
- Different schemes have problems with one or more of the following:
  - Sensitivity to noise and outliers
  - Difficulty handling different sized clusters and convex shapes
  - Breaking large clusters

# MST: Divisive Hierarchical Clustering

- Build MST (Minimum Spanning Tree)
  - Start with a tree that consists of any point
  - In successive steps, look for the closest pair of points (p, q) such that one point (p) is in the current tree but the other (q) is not
  - Add q to the tree and put an edge between p and q

# MST: Divisive Hierarchical Clustering

- Use MST for constructing hierarchy of clusters

---

**Algorithm 7.5** MST Divisive Hierarchical Clustering Algorithm

---

- 1: Compute a minimum spanning tree for the proximity graph.
  - 2: **repeat**
  - 3:   Create a new cluster by breaking the link corresponding to the largest distance (smallest similarity).
  - 4: **until** Only singleton clusters remain
-
